

Global Male-to-Female Ratio Report

A Comprehensive Demographic Overview

Date: October 2026

1 Introduction

The human sex ratio, typically defined as the number of males per 100 females, is a critical demographic metric that influences societal structures, economic development, and population dynamics. This report provides a comprehensive overview of the global male-to-female ratio, examining its current state, natural variations, and underlying factors shaping these demographics.

2 Global Overview

As of recent demographic estimates, the global sex ratio for the entire population is approximately **101 males to 100 females**. This near-parity is the result of a delicate balance between natural birth ratios and sex-differentiated mortality rates throughout the human lifespan.

2.1 Sex Ratio at Birth

The natural sex ratio at birth is not strictly 1:1. Globally, there is a biological bias favoring males, with approximately **105 boys born for every 100 girls**.

Several hypotheses explain this evolutionary adaptation:

- **Higher male mortality:** Males generally experience higher mortality rates at all stages of life, from infancy to old age. The slight surplus of male births compensates for this disparity, ensuring a roughly equal ratio by reproductive age.
- **Biological factors:** Certain genetic and environmental factors may marginally influence the biological likelihood of conceiving a male or female offspring.

2.2 Sex Ratio by Age Group

The male-to-female ratio fluctuates significantly across different age demographics:

1. **Under 15 years:** The ratio skews male, reflecting the natural birth ratio (approximately 105 to 107 males per 100 females).
2. **15 to 64 years:** The ratio begins to equalize, often hovering around 100 to 102 males per 100 females, as higher male mortality rates begin to offset the initial birth advantage.
3. **65 years and over:** The ratio shifts dramatically in favor of females. Due to longer female life expectancy globally, there are significantly more women than men in older age cohorts (often 80 to 85 males per 100 females, dropping even further in advanced age groups).

3 Regional Variations

While the global average is near parity, significant regional disparities exist due to cultural, economic, and historical factors.

3.1 Regions with a Male Surplus

Certain regions, particularly in parts of Asia and the Middle East, exhibit a pronounced male surplus:

- **Middle East:** Countries like Qatar and the United Arab Emirates have exceptionally high male-to-female ratios (sometimes exceeding 200 males per 100 females). This is primarily

driven by a massive influx of male migrant workers in the construction and industrial sectors.

- **Asia:** Historically, strong cultural preferences for male heirs in densely populated nations, combined with the availability of sex-selective technologies, led to skewed sex ratios at birth in previous decades, resulting in a measurable demographic surplus of men today.

3.2 Regions with a Female Surplus

Conversely, other regions feature a higher proportion of females:

- **Eastern Europe:** Several nations in Eastern Europe have a significantly lower male-to-female ratio (around 85 to 90 males per 100 females). This disparity is largely attributed to persistently high adult male mortality rates linked to cardiovascular issues, lifestyle factors, and occupational hazards, compounding historical deficits.
- **Western Europe and North America:** These regions generally display a slight female majority, primarily reflecting the natural advantage in female life expectancy within developed healthcare systems.

4 Factors Influencing the Sex Ratio

Several dynamic factors continually shape and alter sex ratios within populations:

- **Biological and Genetic:** The established baseline 105:100 birth ratio.
- **Mortality Rates:** Differential survival rates, where females typically outlive males due to biological resilience and behavioral factors, as males statistically tend to engage in higher-risk occupations and behaviors.
- **Migration:** Large-scale, sex-selective migration can drastically alter the demographic landscape of both origin and destination countries.
- **Conflict and War:** Major conflicts historically and disproportionately increase male mortality, leading to long-term deficits of men in affected generational cohorts.

5 Conclusion

The global male-to-female ratio is a dynamic indicator, reflecting a complex interplay of biology, economics, and history. While the global aggregate remains close to 1:1, examining the data by age and region reveals a highly nuanced demographic reality. Understanding these variations is essential for policymakers addressing issues ranging from healthcare and pension planning to labor market dynamics and social stability.
